## 1 Representations, L-functions and Artin Twists

### 1.1 Artin Representations and $\ell$ -adic Representations

The Birch-Swinnerton-Dyer conjecture classically provides a connection between the arithmetic of elliptic curves and their  $L$ -functions. In this preliminary section, we explore the classical definition of  $L$ -functions attached to an elliptic curve and their twists, and we explore some of the relevant properties that we will use later on. To do so, we first need to explore the notion of an Artin representation and of an  $\ell$ -adic representation.

Throughout this section we fix a field  $K$ , which will either be a number field or a local field of characteristic 0. We also fix an algebraic closure  $\bar{K}$  of  $K$  and we denote by  $G_K$  the absolute galois group  $\text{Gal}(\bar{K}/K)$  of  $K$ . We recall that  $G_K$  is a profinite group

$$G_K = \varprojlim_F \text{Gal}(F/K),$$

where  $F$  ranges over the finite Galois extensions of  $K$  and therefore has a natural topology where a basis of open sets is given by  $\text{Gal}(\bar{K}/F)$  where  $F$  is a finite extension of  $K$ .

**Definition 1.1.** Let  $K$  be a number field or a local field with characteristic 0. An **Artin representation**  $\rho$  over  $K$  is a complex finite-dimensional vector space  $V$  together with a homomorphism  $\rho : G_K \rightarrow \text{GL}(V) = \text{GL}_n(\mathbb{C})$  such that there is some finite Galois extension  $F/K$  with  $\text{Gal}(\bar{K}/F) \subseteq \ker \rho$ . In other words,  $\rho$  factors through  $\text{Gal}(F/K)$  for some finite extension  $F$  of  $K$ .

Hence, an Artin representation can be equivalently viewed as a finite dimensional representation of  $\text{Gal}(F/K)$  where  $F$  is some finite Galois extension of  $K$ . Throughout the document, we will use both notions depending of the context, and refer to either of them as Artin representations.

**Remark 1.2.** The condition above that  $\text{Gal}(\bar{K}/F) \subseteq \ker \rho$  is equivalent to  $\ker \rho$  being open in  $G_K$ . This clearly implies that  $\rho$  is a continuous homomorphism of topological groups. Surprisingly, the converse is also true: a continuous homomorphism  $\rho : G_K \rightarrow \text{GL}_n(\mathbb{C})$  has open kernel. The proof of this result relies on the fact that ‘small’ neighbourhoods of the identity in  $\text{GL}(V) = \text{GL}_n(\mathbb{C})$  do not contain any non-trivial subgroups. Hence, if  $\phi : G_K \rightarrow \text{GL}(V)$  is continuous and  $U$  is such a neighbourhood in  $\text{GL}(V)$ , then  $\phi^{-1}(U) \subseteq \ker \phi$  and  $\phi^{-1}(U)$  is open, showing that  $\ker \rho$  is open too. Hence the above condition is equivalent to continuity of  $\rho$  with respect to the natural topologies.

Next, we define the notion of an  $\ell$ -adic representation, which will be needed to define the  $L$ -function of an elliptic curve.

**Definition 1.3.** Let  $K$  be a number field or a local field of characteristic 0. A **continuous  $\ell$ -adic representation**  $\rho$  over  $K$  is a continuous homomorphism  $\rho : G_K \rightarrow \mathrm{GL}_n(F)$  where  $F$  is a finite extension of  $\mathbb{Q}_\ell$ .

**Remark 1.4.** The topologies on  $\mathrm{GL}_n(\mathbb{C})$  and  $\mathrm{GL}_n(\mathbb{Q}_\ell)$  are very different, and in particular an  $\ell$ -adic representation may not have an open kernel. Instead, continuity is equivalent to the following condition: for every  $m \geq 1$ , there is some finite field extension  $F_m$  of  $K$  such that for all  $g \in \mathrm{Gal}(\bar{K}/F_m)$ ,  $\rho(g) \equiv \mathrm{Id}_n \pmod{\ell^m}$ .

Given an Artin representation  $\rho$ , one can view it as homomorphism  $\rho : G_K \rightarrow \mathrm{GL}_n(\bar{\mathbb{Q}})$  and since it factors through a finite quotient, we can realise it as  $\rho : G_K \rightarrow \mathrm{GL}_n(F)$  for some number field  $F$ . Hence, if  $\ell$  is any rational prime and  $\mathfrak{l}$  is a prime in  $F$  above  $\ell$ , then one can realise  $\rho$  as an  $\ell$ -adic representation

$$\rho : G_K \longrightarrow \mathrm{GL}_n(F_{\mathfrak{l}}),$$

which is continuous since  $\rho$  factors through a finite quotient. Furthermore, Artin and  $\ell$ -adic representations over  $K$  have more structure; namely, one can take **direct sums** and **tensor products**.

We describe the construction for Artin representations, since the  $\ell$ -adic case is completely analogous. Suppose we have two Artin representations  $\rho_1, \rho_2$  over  $K$ , and by the discussion on the preceding paragraph we can realise them as maps  $\rho_i : G_K \rightarrow \mathrm{GL}_{n_i}(L_i)$ ,  $i = 1, 2$  where  $L_1$  and  $L_2$  are number fields. If we let  $L = L_1 L_2$ , then the natural maps  $\rho_1 \oplus \rho_2 : G_K \rightarrow \mathrm{GL}_{n_1+n_2}(L)$  and  $\rho_1 \otimes \rho_2 : G_K \rightarrow \mathrm{GL}_{n_1 n_2}(L)$  are both Artin representations. One can also show that this construction is also well-defined up to equivalence.

## 1.2 Local Polynomials and L-functions

We now briefly discuss how to attach analytic objects to Artin and  $\ell$ -adic representations. These objects are usually described locally first, and then this local information is put together to get a global object.

To begin, let  $K$  be a local field with 0 characteristic and let  $p$  be the characteristic of the residue field  $\kappa$ . Let  $\rho : G_K \rightarrow \mathrm{GL}(V)$  be an Artin or  $\ell$ -adic representation such that  $\ell \neq p$  (this is an important technical assumption that we will not discuss further). By the **section on algebraic number theory** we have a short exact sequence

$$0 \longrightarrow I_K \longrightarrow \mathrm{Gal}(\bar{K}/K) \xrightarrow{\epsilon} \mathrm{Gal}(\bar{\kappa}/\kappa) \cong \tilde{\mathbb{Z}} \longrightarrow 0,$$

where under the last isomorphism  $1 \in \tilde{\mathbb{Z}}$  corresponds to the map  $\phi : \bar{\kappa} \rightarrow \bar{\kappa}$  where  $x \mapsto x^p$  and this map is a topological generator of  $\mathrm{Gal}(\bar{\kappa}/\kappa)$ . Any preimage of  $\phi$  under  $\epsilon$  is called a Frobenius element  $\mathrm{Frob}_K$  and it is therefore well-defined up to  $I_K$ . Furthermore, the space of inertia-invariants

$$V^{I_K} := \{v \in V : \rho(g)v = v \text{ for all } g \in I_K\}$$

is naturally a  $G_K/I_K$  representation, which we denote  $\rho^{I_K}$ . we are now ready to define the local polynomial attached to  $\rho$ .

**Definition 1.5.** Let  $K$  be a local field of characteristic 0 and let  $p$  the characteristic of its local field. If  $\rho$  is an Artin or  $\ell$ -adic representation such that  $\ell \neq p$ . Then the local polynomial attached to  $\rho$  is

$$P(\rho, T) := \det \left( I - T \cdot \rho^{I_K} (\text{Frob}_K^{-1}) \right).$$

If  $K$  is instead a number field, the idea is to consider all finite places of  $K$  and consider all the local polynomials attached to all local completions of  $K$  to build the corresponding L-function. More concretely, let  $\rho : G_K \rightarrow \text{GL}(V)$  be an Artin or  $\ell$ -adic representation and let  $\mathfrak{p}$  be a finite place of  $K$  and  $K_{\mathfrak{p}}$  be the corresponding completion. Since  $G_{K_{\mathfrak{p}}} = \text{Gal}(\bar{K}_{\mathfrak{p}}/K_{\mathfrak{p}})$  is naturally a subgroup of  $G_K$ , we can restrict  $\rho$  to  $\text{Res}_{\mathfrak{p}}\rho : G_{K_{\mathfrak{p}}} \rightarrow \text{GL}(V)$  and then calculate the corresponding local polynomial as long as  $\mathfrak{p}$  and  $\ell$  are coprime. If  $\rho$  is an Artin representation, this allows us to construct the associated  $L$ -function.

**Definition 1.6.** Let  $K$  be a number field and  $\rho$  an Artin representation over  $K$ . If  $\mathfrak{p}$  is a finite place of  $K$ , we denote the local polynomial at  $\mathfrak{p}$  as

$$P_{\mathfrak{p}}(\rho, T) := P(\text{Res}_{\mathfrak{p}}\rho, T).$$

The associated  $L$ -function to  $\rho$  is

$$L(\rho, s) := \prod_{\mathfrak{p} \text{ prime}} \frac{1}{P_{\mathfrak{p}}(\rho, N(\mathfrak{p})^{-s})}.$$

However, if  $\rho$  is an  $\ell$ -adic representation, constructing a global object is harder, since the above method does not yield information at the finite places  $\mathfrak{p}$  that divide  $\ell$ . This motivates the following important definition.

**Definition 1.7.** Let  $\{\rho_{\ell}\}_{\ell \text{ prime}}$  be a family of  $\ell$ -adic representations for each prime  $\ell$ . We then say that  $\{\rho_{\ell}\}_{\ell}$  is a **weakly compatible system of  $\ell$ -adic representations** if for every finite place  $\mathfrak{p}$  of  $K$  and rational primes  $\ell, \ell'$  not divisible by  $\mathfrak{p}$ ,

$$P_{\mathfrak{p}}(\rho_{\ell}, T) = P_{\mathfrak{p}}(\rho_{\ell'}, T)$$

.

When  $\{\rho_{\ell}\}_{\ell}$  is a weakly compatible system of  $\ell$ -adic representations, the local polynomial  $P_{\mathfrak{p}}(\rho_{\ell}, T)$  can be computed using any  $\ell$  not divisible by  $\mathfrak{p}$ . This also allows us to define the  $L$ -function in this context.

**Definition 1.8.** Let  $K$  be a number field and let  $\{\rho_{\ell}\}_{\ell}$  be a weakly compatible system of  $\ell$ -adic representations. Then the  $L$ -function attached to the system is

$$L(\{\rho_{\ell}\}_{\ell}, s) = \prod_{\mathfrak{p} \text{ prime}} \frac{1}{P_{\mathfrak{p}}(\{\rho_{\ell}\}, N(\mathfrak{p})^{-s})}.$$

### 1.3 The Tate Module of an Elliptic Curve and their L-function

Let  $K$  be a number field or a local field with characteristic 0 (**Maybe for this section we should only assume  $K$  is a number field? Otherwise I don't know if it makes sense to talk about their L-function**) and fix an algebraic closure  $\bar{K}$  of  $K$ . Let  $E$  be an elliptic curve defined over  $K$ . To avoid notational confusion, whenever we write  $E$  we refer to all of its  $\bar{K}$  points, while  $E(K)$  refers only to the  $K$ -rational points.

The aim of this section is to describe a procedure to attach an  $L$ -function to a given elliptic curve over  $K$ . In order to achieve this, we will first construct a 2-dimensional  $\ell$ -adic representation attached to  $E$ , and then construct the  $L$ -function as described in the section above. Let  $\ell$  be a rational prime number. For any  $n \geq 1$ , we denote by  $E[\ell^n]$  to be the  $\ell^n$ -torsion points; in other words,  $E[\ell^n]$  is the kernel of the map  $E[\ell^n] : E \rightarrow E$ . We then have the diagram of compatible maps

$$\longrightarrow E[\ell^{n+1}] \xrightarrow{[\ell]} E[\ell^n] \xrightarrow{[\ell]} \cdots \xrightarrow{[\ell]} E[\ell^2] \xrightarrow{[\ell]} E[\ell] \xrightarrow{[\ell]} \{\mathcal{O}_E\}$$

and therefore we can construct the inverse limit of this diagram

$$T_\ell(E) := \varprojlim_n E[\ell^n],$$

denoted as the  $\ell$ -adic Tate module of the elliptic curve  $E$ . By the uniformization theorem, we know that

$$E[\ell^n] \cong \frac{\mathbb{Z}}{\ell^n \mathbb{Z}} \oplus \frac{\mathbb{Z}}{\ell^n \mathbb{Z}}$$

as groups, and therefore

$$T_\ell(E) \cong \mathbb{Z}_\ell \oplus \mathbb{Z}_\ell$$

as  $\mathbb{Z}_\ell$ -modules. In addition, the Tate module carries important extra structure, namely the action of the absolute Galois group  $G_K$ . Since  $E$  is defined over  $K$ , and the multiplication by  $m$  maps are determined by polynomials with coefficients in  $K$ , there is a well-defined additive action  $\psi_n : G_K \rightarrow \text{Aut}_{\mathbb{Z}}(E[\ell^n])$ . Furthermore, one can show that this actions are compatible with the inverse limit diagram of the Tate module. That is, for every  $n \geq 1$  and  $\sigma \in G_K$ , the diagram

$$\begin{array}{ccc} E[\ell^{n+1}] & \xrightarrow{\ell} & E[\ell^n] \\ \downarrow \psi_{n+1}(\sigma) & & \downarrow \psi_n(\sigma) \\ E[\ell^{n+1}] & \xrightarrow{\ell} & E[\ell^n] \end{array}$$

commutes. Therefore, the actions  $\psi_n$  induce an action of  $G_K$  on  $T_\ell(E)$  and since  $T_\ell(E) \cong \mathbb{Z}_\ell \oplus \mathbb{Z}_\ell$ , this corresponds to a 2-dimensional  $\ell$ -adic representations

$$\psi_{E,\ell} : G_K \longrightarrow \text{GL}_2(\mathbb{Z}_\ell) \subseteq \text{GL}_2(\mathbb{Q}_\ell).$$

We will also denote from now on  $\rho_{E,\ell}$  to be the dual representation of  $\psi_{E,\ell}$ . For technical reasons we will not discuss, the  $L$ -function is typically constructed using the later ones.

**Remark 1.9.** The representation above does indeed satisfy the conditions in Remark 1.4. In particular, given any  $n \geq 1$ , the field  $F_n := K(E[\ell^n])$  is a finite extension of  $K$  since it is obtained by attaching finitely many algebraic numbers. By construction,  $\text{Gal}(\bar{K}/F_n)$  acts trivially on  $E[\ell^n]$  and thus  $\rho_{E,\ell}(g) \equiv \text{Id} \pmod{\ell^n}$  for all  $g \in \text{Gal}(\bar{K}/F_n)$ .

Of course, the above construction can be followed by any rational prime  $\ell$ , and this gives a family  $\{\rho_{E,\ell}\}_\ell$ . To build an  $L$ -function as described in the section above, we would need this family to be weakly compatible. Thankfully, this and much more is true, and the next theorem collects the relevant results.

**Theorem 1.10.** *Let  $E$  be an elliptic curve over a number field  $K$  and  $\rho_{E,\ell}$  be the dual representation on  $T_\ell(E)$ . For every finite place  $\mathfrak{p}$  of  $K$ , let  $\kappa_{\mathfrak{p}}$  be the residue field of  $K_{\mathfrak{p}}$ ,  $q_{\mathfrak{p}} = |\kappa_{\mathfrak{p}}|$  and  $a_{\mathfrak{p}} = 1 + q_{\mathfrak{p}} - |\tilde{E}(\kappa_{\mathfrak{p}})|$ . Then for any  $\mathfrak{p}$  not dividing  $\ell$ ,*

$$\begin{aligned} P_{\mathfrak{p}}(\rho_{E,\ell}, T) &= 1 - a_{\mathfrak{p}}T + q_{\mathfrak{p}}T^2, & \text{if } E/K_{\mathfrak{p}} \text{ has good reduction,} \\ &= 1 - T, & \text{if } E/K_{\mathfrak{p}} \text{ has split multiplicative reduction,} \\ &= 1 + T, & \text{if } E/K_{\mathfrak{p}} \text{ has non-split multiplicative reduction,} \\ &= 1, & \text{if } E/K_{\mathfrak{p}} \text{ has additive reduction.} \end{aligned}$$

*In particular, for any  $\ell, \ell'$  not divisible by  $\mathfrak{p}$ ,*

$$P_{\mathfrak{p}}(\rho_{E,\ell}, T) = P_{\mathfrak{p}}(\rho_{E,\ell'}, T),$$

*and so  $\{\rho_{E,\ell}\}$  is a weakly compatible system of  $\ell$ -adic representations.*

This allows us to define the  $L$ -function of an elliptic curve as above.

**Definition 1.11.** Let  $E$  be an elliptic curve over  $K$ . Then the  $L$ -function attached to  $E$  is

$$L(E/K, s) = L(\{\rho_{E,\ell}\}, s) = \prod_{\mathfrak{p} \text{ prime}} \frac{1}{P_{\mathfrak{p}}(\rho_{E,\ell}, N(\mathfrak{p})^{-s})}$$

## 1.4 Artin Twists of $L$ -functions of Elliptic Curves

We have already seen that given an elliptic curve over a number field  $K$ , one can construct the  $L$ -function  $L(E/K, s)$ . However, given an Artin representation  $\rho$  over  $K$ , it is possible to attach more analytic objects, with remarkable arithmetic properties. We outline the main results below, without proofs. **Insert here relevant reference.**

Fix some number field  $K$ , an elliptic curve  $E$  over  $K$  and an Artin representation  $\rho$ . Then, similarly to the previous section, it is possible to show that  $\{\rho_{E,\ell} \otimes \rho\}_{\ell}$  is also a weakly compatible system of  $\ell$ -adic representations. The corresponding  $L$ -function

$$L(E, \rho, s) = L(\{\rho_{E,\ell} \otimes \rho\}, s)$$

is denoted as the **Artin-twist** of  $L(E, s)$  by  $\rho$ . These objects have remarkable (both proven and conjectural) properties that we describe now.

**Theorem 1.12** (Artin Formalism). *Let  $E$  be an elliptic curve over a number field  $K$ .*

1. *For Artin representations  $\rho_1, \rho_2$  over  $K$ ,*

$$L(\rho_1 \oplus \rho_2, s) = L(\rho_1, s)L(\rho_2, s) \quad \text{and} \quad L(E/K, \rho_1 \oplus \rho_2, s) = L(E/K, \rho_1, s)L(E/K, \rho_2, s)$$

2. *If  $L/K$  is a finite extension and  $\rho$  is an Artin representation over  $L$ , then  $\text{Ind}_{G_L}^{G_K} \rho$  is an Artin representation over  $K$  and*

$$L(\rho, s) = L(\text{Ind}_{G_L}^{G_K} \rho, s) \quad \text{and} \quad L(E/L, \rho, s) = L(E/L, \text{Ind}_{G_L}^{G_K} \rho, s).$$

3. If  $L/K$  is a finite extension as above and

$$\mathrm{Ind}_{G_L}^{G_K} \mathbf{1} \cong \bigoplus_i \rho_i,$$

then

$$L(E/L, s) = \prod_i L(E/K, \rho_i, s).$$

To simplify notation, given any Artin representation  $\rho$  over  $L$  we will write  $\mathrm{Ind}_{L/K} \rho$  instead of  $\mathrm{Ind}_{G_L}^{G_K} \rho$ . Furthermore if  $F$  is a finite Galois extension of  $K$  such that  $\rho$  factors through  $\mathrm{Gal}(F/L)$ , then  $\mathrm{Ind}_{L/K} \rho$  factors through  $\mathrm{Gal}(F/K)$  and

$$\mathrm{Ind}_{L/K} \rho \cong \mathrm{Ind}_{\mathrm{Gal}(F/L)}^{\mathrm{Gal}(F/K)} \rho.$$

Furthermore, as mentioned after Remark 1.4, by fixing some basis  $\mathcal{B}$  of  $V$  any Artin representation  $\rho$  can be viewed as a representation  $\rho : G_K \rightarrow \mathrm{GL}_n(F)$  for some number field  $F$ . The smallest such field is the **field of values** of  $\rho$  and denoted by  $\mathbb{Q}(\rho)$ . Any  $\sigma \in \mathrm{Gal}(\mathbb{Q}(\rho)/\mathbb{Q})$  induces a homomorphism  $\sigma : \mathrm{GL}_n(\mathbb{Q}(\rho)) \rightarrow \mathrm{GL}_n(\mathbb{Q}(\rho))$  and also a map

$$\begin{aligned} \rho^\sigma : G_K &\longrightarrow \mathrm{GL}_n(F) \\ g &\longmapsto \sigma(\rho(g)), \end{aligned}$$

which is another Artin representation, denoted as the twist of  $\rho$  by  $\sigma$ .

**Conjecture 1.13** (Galois Equivariance of L-Twists). I need to check the precise statement of this result. This may need to come after the discussion on BSD.

## 2 Birch and Swinnerton-Dyer and Other Conjectures

The Birch-Swinnerton-Dyer conjecture classically provides a connection between the arithmetic of elliptic curves and their  $L$ -functions. We have already investigated the construction and main results of the ‘ $L$ -functions side’, and now we turn our attention to statement of the conjecture and towards understanding the arithmetic terms present in the conjecture.

**Conjecture 2.1** (BSD). Let  $E$  be an elliptic curve over a number field  $K$ . Then

**BSD1.** The rank of the Mordell-Weil group of  $E$  over  $K$  equals the order of vanishing of the  $L$ -function; that is,

$$\mathrm{ord}_{s=1} L(E/K, s) = \mathrm{rk} E/K.$$

**BSD2.** The leading term of the Taylor series at  $s = 1$  of the  $L$ -function is given by

$$\lim_{s \rightarrow 1} \frac{L(E/K, s)}{(s-1)^r} \cdot \frac{\sqrt{|\Delta_K|}}{\Omega_+(E)^{r_1+r_2} |\Omega_-(E)|^{r_2}} = \frac{\mathrm{Reg}_{E/K} |\mathrm{III}_{E/K}| C_{E/K}}{|E(K)_{\mathrm{tors}}|^2}. \quad (1)$$

Many arithmetic invariants appear as part of the statement of BSD2, and it is worth exploring them briefly. The way we have organised the terms is not arbitrary, and in fact we give specific notation to both sides of the equation.

**Notation 2.2.** Let  $E/\mathbb{Q}$  be a number field and  $K$  a number field. We define

$$\mathcal{L}(E/F) = \lim_{s \rightarrow 1} \frac{L(E/K, s)}{(s-1)^r} \cdot \frac{\sqrt{|\Delta_K|}}{\Omega_+(E)^{r_1+r_2} |\Omega_-(E)|^{r_2}}$$

and

$$\text{BSD}(E/F) = \frac{\text{Reg}_{E/K} |\text{III}_{E/K}| C_{E/K}}{|E(K)_{\text{tors}}|^2}$$

A natural question to ask at this point is whether there is a conjectural analogue to the above for the Artin twists of  $L$ -functions. The analogue of BSD1 is known in this case, which is directly compatible with Artin formalism.

**Conjecture 2.3** (BSD1 for Twists). Let  $E/\mathbb{Q}$  be an elliptic curve,  $\rho$  an Artin representation and  $K$  any Galois extension over  $\mathbb{Q}$  such that  $\rho$  factors through  $G = \text{Gal}(K/\mathbb{Q})$ . Then

$$\text{ord}_{s=1} L(E, \rho, s) = \langle \rho, E(K)_\mathbb{C} \rangle_G$$

**maybe delete this last sentence.** where  $\rho$  and  $E(K)_\mathbb{C} = E(K) \otimes_{\mathbb{Z}} \mathbb{C}$  are viewed as representations of  $G$ .

Unfortunately, a conjectural analogue for BSD2 is not known. The problem is the lack of an analogue for the term  $\text{BSD}(E/F)$  as above. However, there is indeed an important analogue of the term  $\mathcal{L}(E/F)$  in this setting.

**Notation 2.4.** Let  $E/\mathbb{Q}$  be an elliptic curve and  $\rho$  an Artin representation over  $\mathbb{Q}$ . We define

$$\mathcal{L}(E, \rho) = \lim_{s \rightarrow 1} \frac{L(E, \rho, s)}{(s-1)^r} \cdot \frac{\sqrt{\mathfrak{f}_\rho}}{\Omega_+(E)^{d^+(\rho)} |\Omega_-(E)|^{d^-(\rho)} \omega_\rho},$$

where  $r = \text{ord}_{s=1} L(E, \rho, s)$  is the order of the zero at  $s = 1$ ,  $\mathfrak{f}_\rho$  is the conductor of  $\rho$ , and  $d^\pm(\rho)$  are the dimensions of the  $\pm 1$ -eigenspaces of complex conjugation in its action on  $\rho$ .

Even though the precise conjectural expression of the  $\text{BSD}(E, \rho)$  is not known, they conjecturally satisfy many important properties. The next conjecture lists some of these properties.

**Conjecture 2.5.** [DEW21, Conjecture 4] Let  $E/\mathbb{Q}$  be an elliptic curve. For every Artin representation  $\rho$  over  $\mathbb{Q}$  there is an invariant  $\text{BSD}(E, \rho) \in \mathbb{C}^\times$  with the following properties. Let  $\rho$  and  $\tau$  be Artin representations and  $K$  a finite extension of  $\mathbb{Q}$  such that  $\rho$  and  $\tau$  factor through  $\text{Gal}(K/\mathbb{Q})$ .

**C1.**  $\text{BSD}(E/F) = \text{BSD}(E, \text{Ind}_{F/\mathbb{Q}} \mathbf{1})$  for a number field  $F$  (and  $\text{III}_{E/F}$  is finite).

**C2.**  $\text{BSD}(E, \rho \oplus \tau) = \text{BSD}(E, \rho) \text{BSD}(E, \tau)$ .

**C3.**  $\text{BSD}(E, \rho) = \text{BSD}(E, \rho^*) \cdot (-1)^r \omega_{E, \rho} \omega_\rho^{-2}$ , where  $r = \langle \rho, E(K)_\mathbb{C} \rangle$ .

**C4.** If  $\rho$  is self-dual, then  $\text{BSD}(E, \rho) \in \mathbb{R}$  and  $\text{sign } \text{BSD}(E, \rho) = \text{sign } \omega_\rho$ .

If  $\langle \rho, E(K)_\mathbb{C} \rangle = 0$ , then moreover:

**C5.**  $\text{BSD}(E, \rho) \in \mathbb{Q}(\rho)^\times$  and  $\text{BSD}(E, \rho^g) = \text{BSD}(E, \rho)^g$  for all  $g \in \text{Gal}(\mathbb{Q}(\rho)/\mathbb{Q})$ .

**C6.** If  $\rho$  is a non-trivial primitive Dirichlet character of order  $d$ , and either the conductors of  $E$  and  $\rho$  are coprime or  $E$  is semistable and has no non-trivial isogenies over  $\mathbb{Q}$ , then  $\text{BSD}(E, \rho) \in \mathbb{Z}[\zeta_d]$ .

The great advantage of the above conjecture is that it is free of  $L$ -functions since only the ‘arithmetic’  $\text{BSD}(E/F)$  terms appear. Conditional to some well-known conjectures, Conjecture 2.5 holds.

**Theorem 2.6.** [DEW21, Theorem 5] *Conjecture 4 holds with  $\text{BSD}(E, \rho) = \mathcal{L}(E, \rho)$  assuming the analytic continuation of  $L$ -functions  $L(E, \rho, s)$ , their functional equation, the Birch-Swinnerton-Dyer conjecture, Deligne’s period conjecture, Stevens’s Manin constant conjecture for  $E/\mathbb{Q}$  and the Riemann hypothesis for  $L(E, \rho, s)$ .*

### 3 Brauer Relations

### 4 Predicting Positive Rank

At this point, we aim to study the arithmetic applications of Conjecture 2.5. Some of these applications are already studied in [DEW21, §3], and it allows to predict non-trivial interplay of the primary parts of the Tate-Shafarevich group of families of elliptic curves, non-trivial Selmer groups and even positive rank. All of these results appear not to be tractable with other common current methods.

The most interesting case is the prediction of positive rank for families of elliptic curves on certain number fields. We illustrate the proof of the main result that predict positive rank conditional on Conjecture 2.5. Let  $F$  be a Galois extension over  $\mathbb{Q}$  and let  $G = \text{Gal}(F/\mathbb{Q})$ . Let  $E/\mathbb{Q}$  be an elliptic curve and let  $\rho$  be an irreducible representation over  $G$ , which we view as an Artin representation. Then the representation

$$\bigoplus_{\mathfrak{g} \in \text{Gal}(\mathbb{Q}(\rho)/\mathbb{Q})} \rho^{\mathfrak{g}}$$

has  $\mathbb{Q}$ -valued character and therefore there is some  $m \geq 1$  and subfields  $F_i, F'_j$  such that

$$\left( \bigoplus_{\mathfrak{g} \in \text{Gal}(\mathbb{Q}(\rho)/\mathbb{Q})} \rho^{\mathfrak{g}} \right)^m \oplus \bigoplus_j \text{Ind}_{F'_j/\mathbb{Q}} \mathbb{1} = \bigoplus_i \text{Ind}_{F_i/\mathbb{Q}} \mathbb{1}.$$

Assume that  $\text{rk} E/F = 0$  so that in particular  $\langle \rho, E(F)_\mathbb{C} \rangle_G = 0$ . Therefore (C1), (C2) and (C5) from Conjecture 2.5 imply that

$$\frac{\prod_i \text{BSD}(E/F_i)}{\prod_j \text{BSD}(E/F'_j)} = \frac{\prod_i \text{BSD}(E, \text{Ind}_{F_i/\mathbb{Q}} \mathbb{1})}{\prod_j \text{BSD}(E, \text{Ind}_{F'_j/\mathbb{Q}} \mathbb{1})} = \left( \prod_{\mathfrak{g} \in \text{Gal}(\mathbb{Q}(\rho)/\mathbb{Q})} \text{BSD}(E, \rho)^{\mathfrak{g}} \right)^m \quad (2)$$

and the right-hand side is clearly the  $m$ -th power of a norm of an element in  $\mathbb{Q}(\rho)$ .

The product of BSD terms on the LHS of (2) involve regulators, the torsion subgroups, the Tate-Shafarevich groups and the terms  $C_{E/F}$  which are the product of local factors. Under the assumption that  $\text{rk} E/F = 0$ , the regulators vanish from the product. In general, it is very difficult to deal with the size of the Tate-Shafarevich group for families of elliptic curves, and therefore very difficult to know if the LHS is an  $m$ -th power the norm of an element in  $\mathbb{Q}(\rho)$ . However, not all hope is lost, since Cassel's proved the following.

**Theorem 4.1.** *Let  $E$  be an elliptic curve over a number field  $K$ . If  $\text{III}_{E/K}$  is finite, then  $|\text{III}_{E/K}|$  is a square.*

Rational squares are not necessarily the norms of general number fields, but they are always norms of quadratic number fields. Furthermore, if  $\mathbb{Q}(\sqrt{D})$  is a quadratic subfield fo  $\mathbb{Q}(\rho)$ , then the RHS of (2) is also the norm of an element of  $\mathbb{Q}(\sqrt{D})$  and a rational square if  $m$  is even. Under the assumption of finiteness of  $\text{III}$ , we know that  $|\text{III}_{E/F}|$  and  $|E(F)_{\text{tors}}|^2$  are rational squares and therefore norms of  $\mathbb{Q}(\sqrt{D})$ . The only remaining terms on the LHS of (2) are the product of local factors  $C_{E/F_i}$  and  $C_{E/F'_j}$ . We have therefore proven the following.

**Theorem 4.2.** *[DEW21, Theorem 33] Suppose Conjecture 2.5 holds. Let  $E/\mathbb{Q}$  be an elliptic curve,  $F/\mathbb{Q}$  a finite Galois extension with Galois group  $G$ ,  $\rho$  an irreducible representation of  $G$  and*

$$\left( \bigoplus_{\mathfrak{g} \in \text{Gal}(\mathbb{Q}(\rho)/\mathbb{Q})} \rho^{\mathfrak{g}} \right)^m = \bigoplus_i \text{Ind}_{F_i/\mathbb{Q}} \mathbf{1} \ominus \bigoplus_j \text{Ind}_{F'_j/\mathbb{Q}} \mathbf{1}$$

*for some  $m \geq 1$  and subfields  $F_i, F'_j \subseteq F$ . If either  $\frac{\prod_i C_{E/F_i}}{\prod_j C_{E/F'_j}}$  is not a norm from some quadratic subfield  $\mathbb{Q}(\sqrt{D}) \subseteq \mathbb{Q}(\rho)$ , or if it is not a rational square when  $m$  is even, then  $E$  has a point of infinite order over  $F$ .*

This is a remarkable result, since it can predict positive rank of general families of elliptic curves based solely on local data.

## 5 Consistency cases with BSD

As we discussed in the previous section, our motivation is to use Theorem 4.2 to predict points of infinite order for families of elliptic curves. However, in this section we prove that in several cases the theorem will never make such a prediction. In other words, in such cases, the product

$$\frac{\prod_i C_{E/F_i}}{\prod_j C_{E/F'_j}}$$

is always a norm for every subfield  $\mathbb{Q}(\sqrt{D}) \subseteq \mathbb{Q}(\rho)$ .

### 5.1 Cyclic Extensions

In this subsection we prove the following.

**Theorem 5.1.** *Let  $E/\mathbb{Q}$  be a semistable elliptic curve and let  $F$  a finite cyclic Galois extension over  $\mathbb{Q}$  so that  $\text{Gal}(F/\mathbb{Q}) = C_d$  for some  $d \geq 2$ . Let  $\chi$  be a faithful character of  $C_d$  (so that  $\mathbb{Q}(\chi) = \mathbb{Q}(\zeta_d)$ ), and let  $F_i, F'_j \subseteq F$  be such that*

$$\bigoplus_{\mathfrak{g} \in \text{Gal}(\mathbb{Q}(\zeta_d)/\mathbb{Q})} \chi^{\mathfrak{g}} = \bigoplus_i \text{Ind}_{F_i/\mathbb{Q}} \mathbb{1} \ominus \bigoplus_j \text{Ind}_{F'_j/\mathbb{Q}} \mathbb{1}.$$

*Then for any  $\mathbb{Q}(\sqrt{D}) \subseteq \mathbb{Q}(\zeta_d)$ ,*

$$\frac{\prod_i C_{E/F_i}}{\prod_j C_{E/F'_j}}$$

*is a norm of  $\mathbb{Q}(\sqrt{D})$ .*

The first step in proving Theorem 5.1 is to show that the fields  $F_i, F'_j$  exist, and to give a precise description. Recall that for each  $k \mid d$  the cyclic group  $C_d$  has one unique subgroup of order  $k$ , which is of course also cyclic. Therefore, for each  $k \mid d$ , there is one unique subfield  $F_k$  of  $F$  of degree  $k$  over  $\mathbb{Q}$  which is also cyclic. The corresponding subgroup  $H_k = \text{Gal}(F/F_k) = C_{d/k}$ .

To give the required description, we recall that the Möbius function  $\mu$  is the function supported on the square-free integers, and  $\mu(n) = (-1)^s$  whenever  $n$  is square free and  $s$  is the number of prime factors of  $n$ .

**Lemma 5.2.** *Let  $E/\mathbb{Q}$ ,  $F$  and  $\chi$  be as in Theorem 5.1. Writing characters of  $C_d$  additively, we have that*

$$\sum_{\mathfrak{g} \in \text{Gal}(\mathbb{Q}(\zeta_d)/\mathbb{Q})} \chi^{\mathfrak{g}} = \sum_{k \mid d} \mu(d/k) \text{Ind}_{F_k/\mathbb{Q}} \mathbb{1}. \quad (3)$$

*Proof.* The proof is essentially application of Frobenius reciprocity and the inclusion exclusion lemma. Let  $p_1, \dots, p_s$  be the distinct primes dividing  $d$ . By Frobenius reciprocity, for any character  $\theta$  of  $C_d$  and  $k \mid d$ ,

$$\langle \theta, \text{Ind}_{F_k/\mathbb{Q}} \mathbb{1} \rangle_{C_d} = \langle \text{Res}_{F_k/\mathbb{Q}} \theta, \mathbb{1} \rangle_{C_{d/k}}.$$

That is,  $\theta$  appears as a factor of  $\text{Ind}_{F_k/\mathbb{Q}} \mathbb{1}$  if and only if  $\chi|_{C_{d/k}}$  is trivial, and it can only appear once. Therefore,

$$\text{Ind}_{F_k/\mathbb{Q}} \mathbb{1} = \sum_{\theta \in \mathcal{A}_{d/k}} \theta$$

where  $\mathcal{A}_k = \{\theta \in \widehat{C_d} : \theta|_{C_k} = \mathbb{1}_{C_k}\}$ . Note that if  $k, k' \mid d$  are coprime, then  $\mathcal{A}_k \cap \mathcal{A}_{k'} = \mathcal{A}_{kk'}$ . If  $\mathcal{B}$  is the set of faithful characters of  $C_d$ , then by the inclusion-exclusion lemma

$$\begin{aligned} \sum_{\theta \in \mathcal{B}} \theta &= \sum_{i=0}^s (-1)^i \sum_{1 \leq j_1 \leq \dots \leq j_i \leq s} \sum_{\theta \in \cap_{l=1}^i \mathcal{A}_{p_{j_l}}} \theta \\ &= \sum_{i=0}^s (-1)^i \sum_{1 \leq j_1 \leq \dots \leq j_i \leq s} \sum_{\theta \in \mathcal{A}_{\prod_{l=1}^i p_{j_l}}} \theta \\ &= \sum_{k \mid d} \mu(k) \sum_{\theta \in \mathcal{A}_k} \theta = \sum_{k \mid d} \mu(d/k) \text{Ind}_{F_k/\mathbb{Q}} \mathbb{1}. \end{aligned}$$

The proof now follows from the fact that if  $\chi$  is a faithful character, then the set  $\{\chi^{\mathfrak{g}} : \mathfrak{g} \in \text{Gal}(\mathbb{Q}(\zeta_d)/\mathbb{Q})\}$  spans over all faithful characters of  $C_d$  once.  $\square$
